

Same model, same threshold: nearly twice as many benign lesions flagged on darker skin

full model, full-ITA split, $t = 0.5$ · every lesion shown is benign · score printed under each, dashed line = threshold

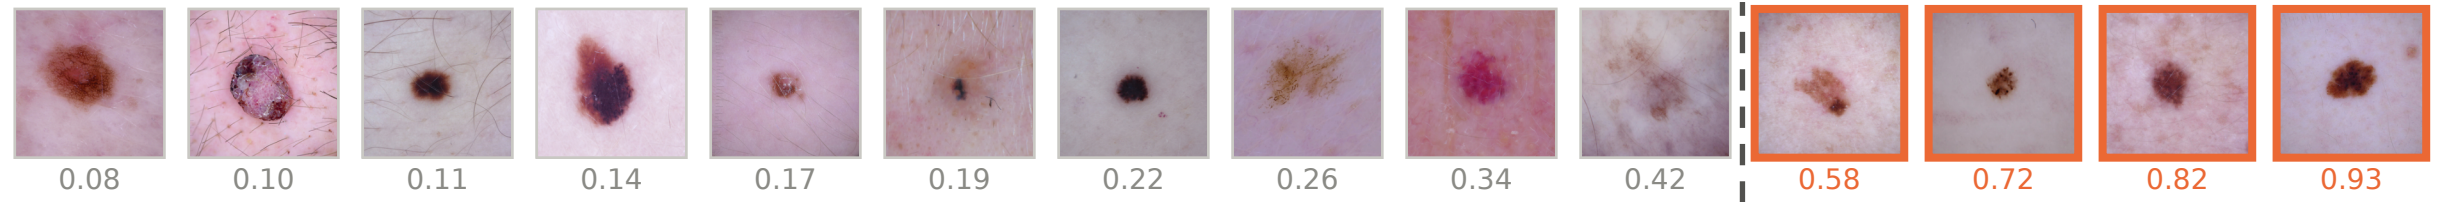

Light skin

ITA > 41° · 15.2% of all 703 benign lesions flagged

Dark skin

ITA ≤ 10° · 28.3% of all 413 benign lesions flagged

Tone is ITA-estimated from background skin, not a ground-truth Fitzpatrick label. Thumbnails are sampled at even quantiles of each group's benign score distribution (14 per row), so the proportion past the threshold reflects the true rate; spacing is even, so position is rank, not score.
